17-423/723: Designing Large-scale Software Systems

Design for Change Feb 3, 2025

Leaning Goals

- Apply principles for improving modularity: Single responsibility, interface segregation, and dependency inversion
- Describe the benefits & limitations of each principle
- Evaluate possible costs of modularity and its impact on other quality attributes

Last Class

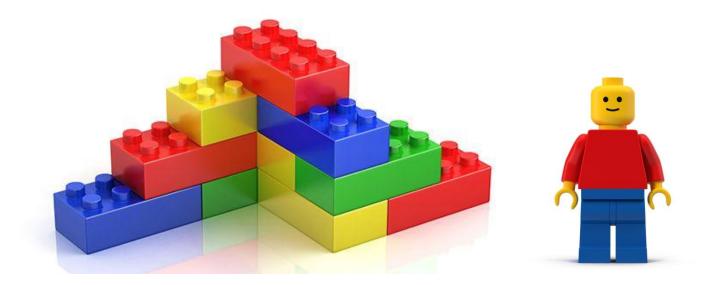

- Changeability
- Information hiding
- Data abstraction
- Interface abstraction
- Encapsulation

Recall: Changeability

- A measure of the amount of effort involved in making a change to a system
- Usually qualitative (i.e., yes/no), but sometimes quantified in terms of numerical metrics (e.g., lines of code changed)
- Quality attribute specifications examples:
 - "A new publisher can be added without having to change any of the existing subscribers"
 - "New types of stocks can be added without changing the format of how each stock is displayed"
 - "Improving the performance of the C++ compiler does not affect the parser"
 - "Adding a new type of sensor in a self-driving vehicle requires changing only the image processing module"

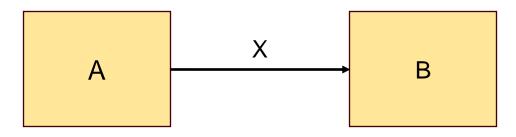

Related Concepts

- Modularity
 - Degree to which different parts of the system can be substituted with alternative parts without affecting the rest of the system
 - Closely related to changeability: Modularity supports changeability!

Dependency

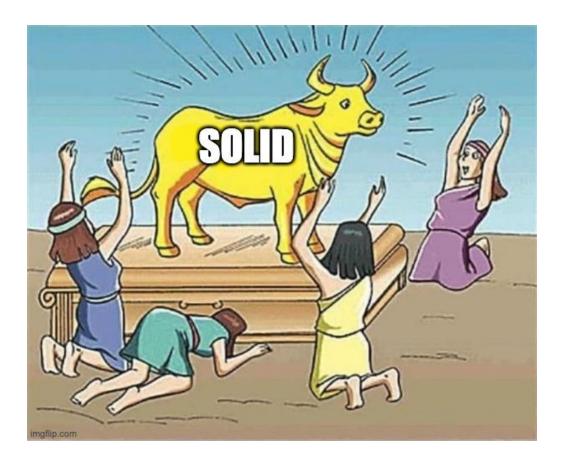

- Degree to which one component relies on another component to fulfill its responsibility
- To fulfill its responsibility, component A depends on B through connection X
- If B changes in a way that affects X, A may need to change to continue fulfilling its responsibility
- Information hiding: Hide secrets (design decisions) that are likely to change from other components

Today's Class

- Other principles for improving the modularity (and changeability) of the system
- SOLID principles
 - Single-responsibility principle
 - Open-closed principle
 - Liskov substitution principle
 - Interface segregation principle
 - Dependency inversion principle

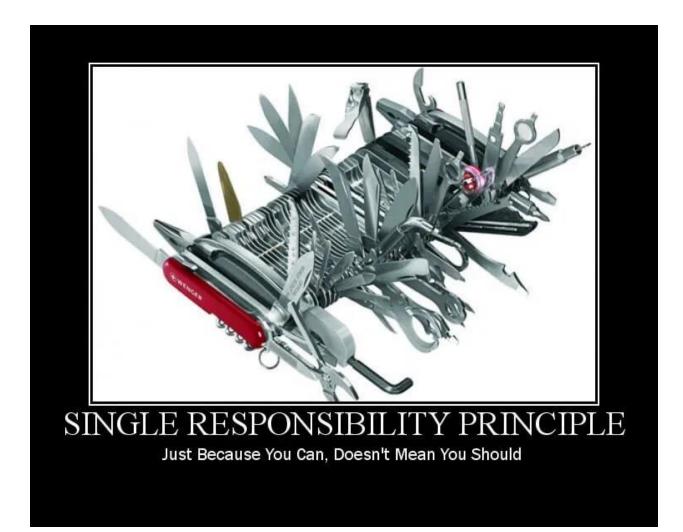

A word of caution...

- People tend to get attached to trendy/popular ideas
- SOLID encodes good design practices, but are NOT a solution to every design problem
- Even good ideas, when applied blindly, can result in harmful outcome
- Think of these as tools! Ultimately, you need to apply your own judgement on when these are helpful or not

Single Responsibility Principle

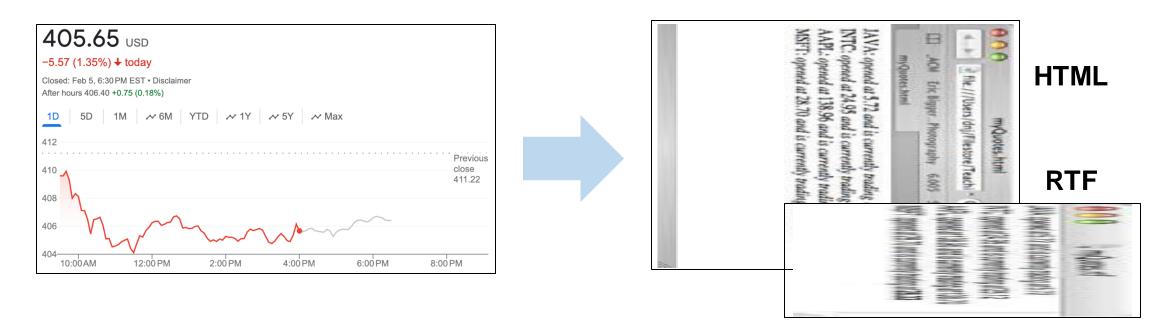

Single Responsibility Principle (SRP)

Single Responsibility Principle (SRP)

- Each component should be responsible for fulling a single purpose only
 - Purpose: A unit of functionality, a use case, or a quality attribute
 - A purpose is associated with one or more design decision(s)
- Corollary: A component should not be designed to serve multiple purposes
 - Such a component may contain multiple secrets (i.e., design decisions) for different purposes
 - This encourages those secrets to become intermingled & dependent on each other; harder to change independently!
 - Such a component should be separated into multiple components

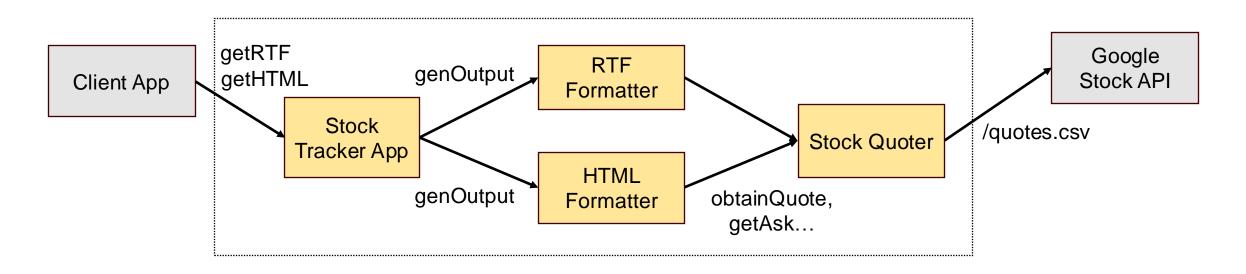

Recall: Stock Tracker App

- Get a list of stock quotes (prices) from an external source (e.g., Google)
- Produce output in HTML or RTF format
- Put the quote in **bold** if the change since the opening is > 1%

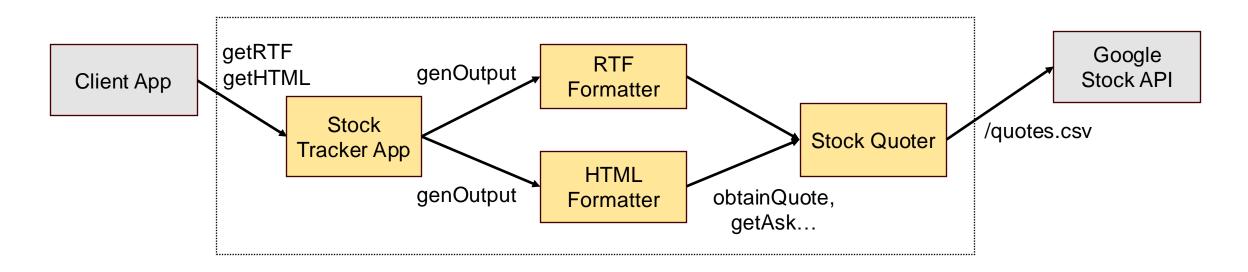

Based on an example by Daniel Jackson & Rob Miller

Stock Tracker: Violation of SRP?

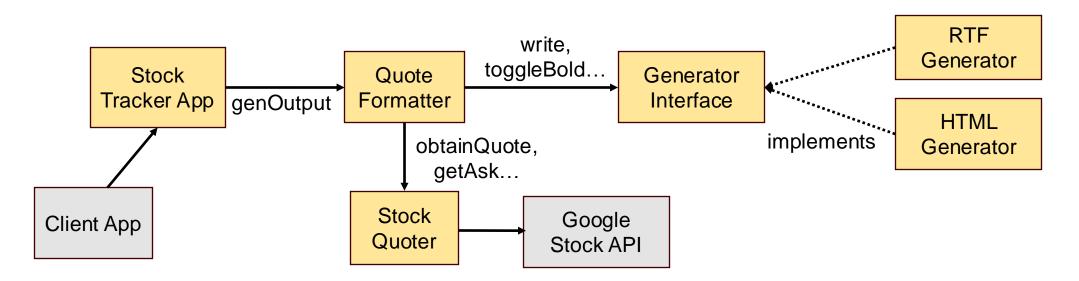

- Stock Trakcer App: Fulfills requests from a client for a quote in a certain format
- RTF/HTML formatter: Get quote from Stock Quoter & generate output in the right format
- Stock Quoter: Invoke Google API to get quote & return the result to Formatter
- Q. Does this design violate SRP?

Stock Tracker: Violation of SRP?

- **Problem**: HTML/RTF Formatters know (1) how to generate HTML/RTF elements in different formats and (2) what should be bolded, underlined, etc.,
- (2) is a design decision that can be separated & hidden from components that generate HTML/RTF!

Stock Tracker App: New Design

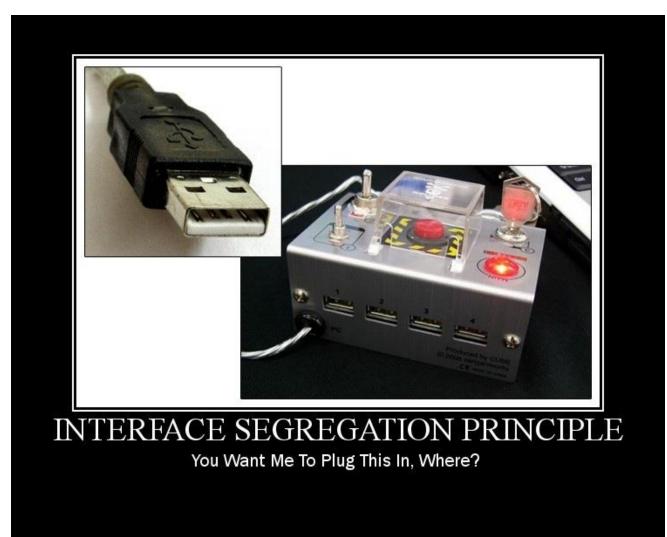

- HTML/RTF Generator: Writes & formats a given string using HTML/RTF tags
- Formatter: Encodes which part of the quote should be bolded, italicized
- Generators and Formatter now serve separate responsibilities!

Single Responsibility Principle (SRP)

- Each component should be responsible for fulling a single purpose only
- **Benefits**: Single-responsibility (SR) components
 - Reduce dependency between design decisions; make it easier to change them independently
 - Are more reusable: Provide a distinct unit of purpose that can be reused in other contexts
 - Are easier to understand & test
- Q. Limitations or dangers of SRP?

Interface Segregation Principle

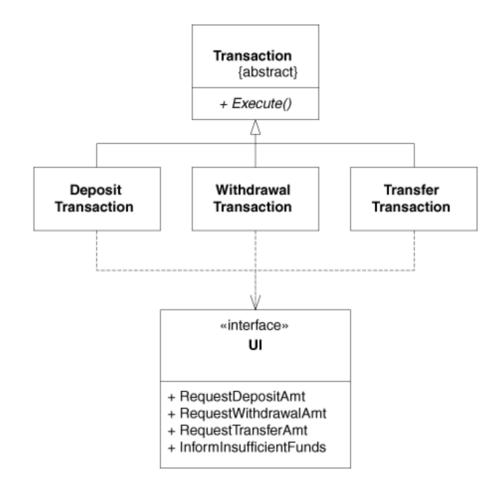

Interface Segregation Principle (ISP)

Interface Segregation Principle (ISP)

- An interface should not force clients to depend on unnecessary details
- Interface pollution: A common issue that arises when an interface grows & serves tasks for different types of clients

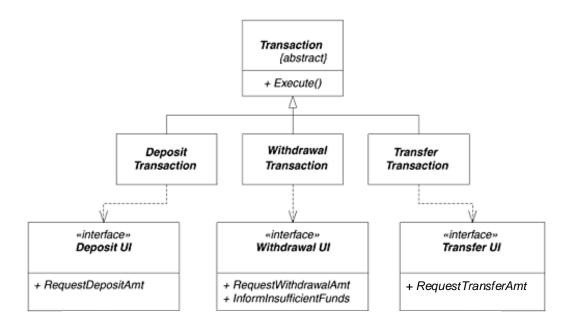

Example: ATM User Interface

- Different types of transactions require different user interactions
- Some UI methods are only used by a single transaction
- Q. What could go wrong here?
- Dependencies between transactions through the interface!
 - If a change in a transaction involves changes to the UI, these could cause changes in other transactions
- Q. What can we do to mitigate this issue?

Example from: Agile Principles, Patterns, and Practices in C# by Martin & Matin (2007)

Example: ATM User Interface

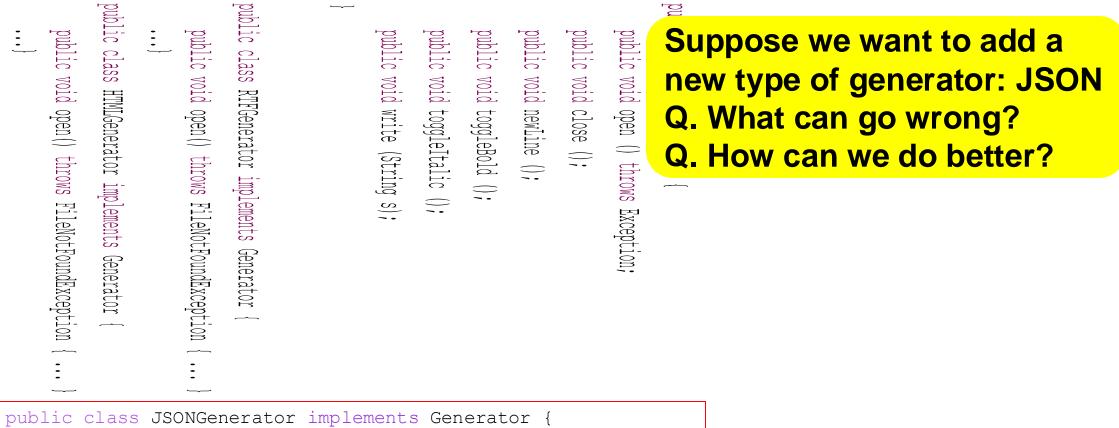

• An alternative design: Decompose the bloated interface into multiple, separate interfaces

• Benefits:

- Each interface serves one particular type of client
- Each interface does not force the client to depend on unnecessary details
- Each interface (its client) can change independently from other interfaces

Another Example: Stock Tracker

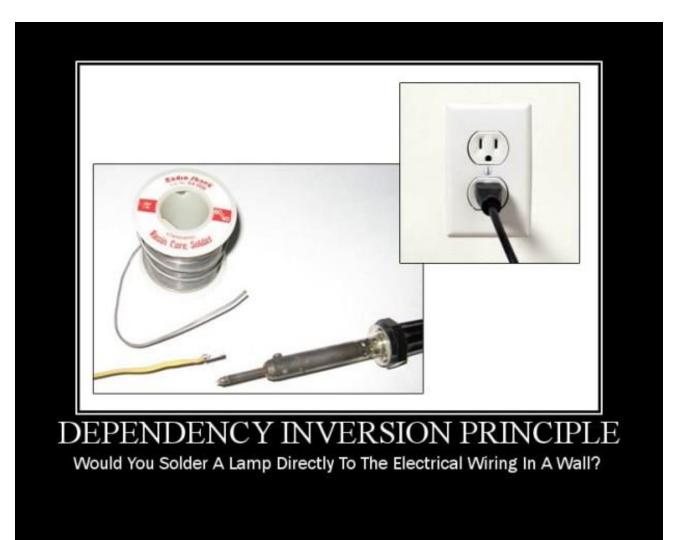

public void open() throws FileNotFoundException { ... }
...}

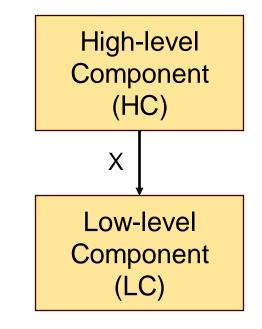

.

Interface Segregation Principle (ISP)

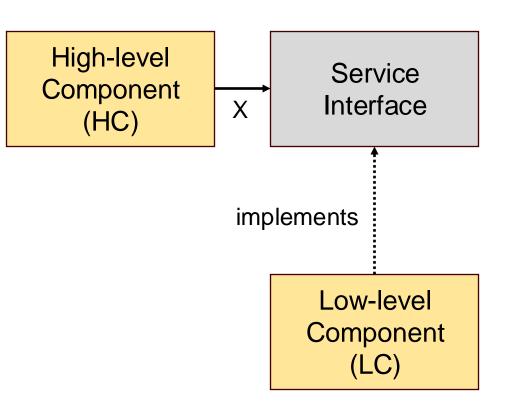

- An interface should not force clients to depend on unnecessary details
- Interface pollution: A common issue that arises when an interface grows & serves tasks for different types of clients
- Decompose the bloated interface into separate interfaces, each exposing details that are needed only by a single client
- Q. What is the relationship between ISP and single responsibility principle (SRP)?

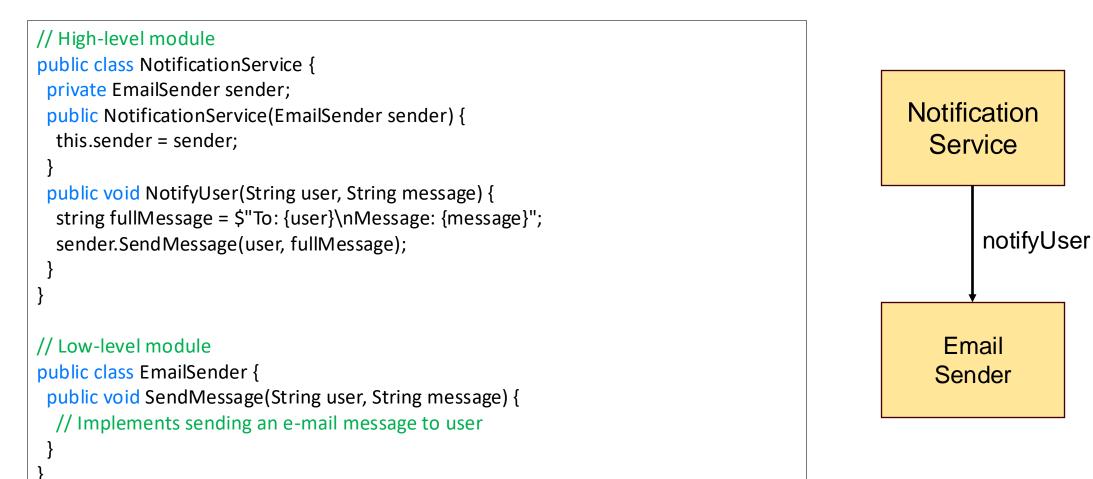

- Idea: A "high-level" component should not depend on a "low-level" component
- High-level components (**HC**): Responsible for the core application logic and use cases
- Low-level components (LC): Services or libraries that serve the core logic

- Invert the dependency from HC to LC by introducing an intermediate abstraction (e.g., an interface)
 - Recall: Interface abstraction!
- Interface provides abstract operations & data that are needed by HC
- HC & LC both depend this abstraction
- HC does not directly interact with LC
- Goal: When LC changes, minimize its impact on HC

// Abstraction

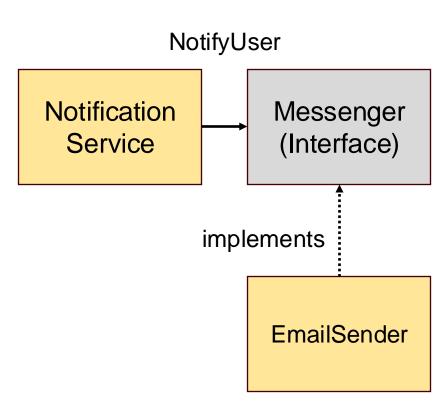

public interface Messenger {
 void SendMessage(String user, String message);

// High-level module

public class NotificationService { private Messenger sender; public NotificationService(Messenger sender) { this.sender = sender;

public void NotifyUser(String user, String message) {
 string fullMessage = \$"To: {user}\nMessage: {message}";
 sender.SendMessage(user, fullMessage);

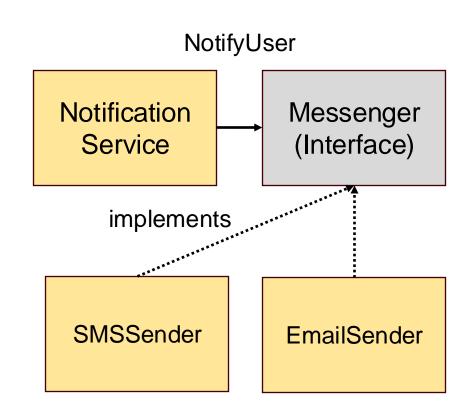

// Low-level module
public class EmailSender implements Messenger {
public void SendMessage(string user, string message)
// Implements sending an e-mail message to user

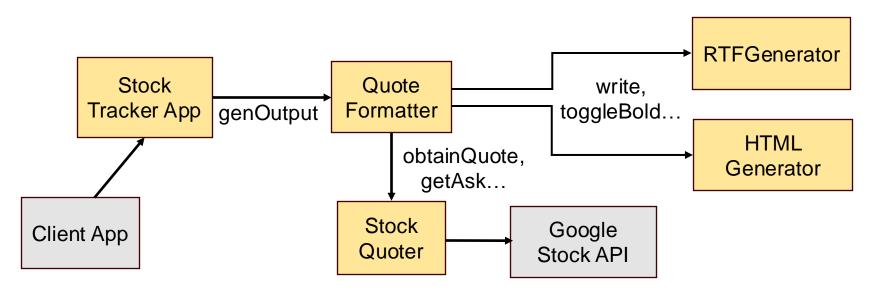

// Abstraction NotifyUser public interface Messenger { void SendMessage(String user, String message); Notification Messenger // High-level module (Interface) Service public class NotificationService { private Messenger sender; public NotificationService(Messenger sender) { this.sender = sender; implements public void NotifyUser(String user, String message) { string fullMessage = \$"To: {user}\nMessage: {message}"; sender.SendMessage(user, fullMessage); EmailSender // Low-level module public class EmailSender implements Messenger { public void SendMessage(string user, string message) { // Implements sending an e-mail message to user

// Abstraction public interface Messenger { void SendMessage(String user, String message); // High-level module public class NotificationService { private Messenger sender; public NotificationService(Messenger sender) { this.sender = sender; public void NotifyUser(String user, String message) { string fullMessage = \$"To: {user}\nMessage: {message}"; sender.SendMessage(user, fullMessage);

// Low-level module
public class SmsSender implements Messenger {
 public void SendMessage(string user, string message) {
 // Implements sending an SMS message to user

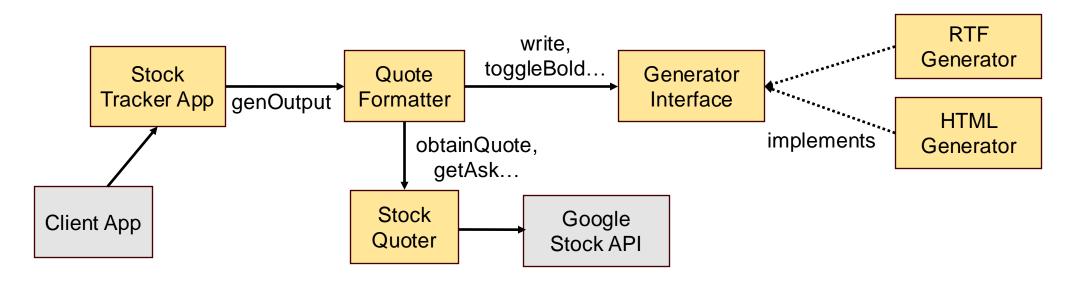

Stock Tracker App: New Design

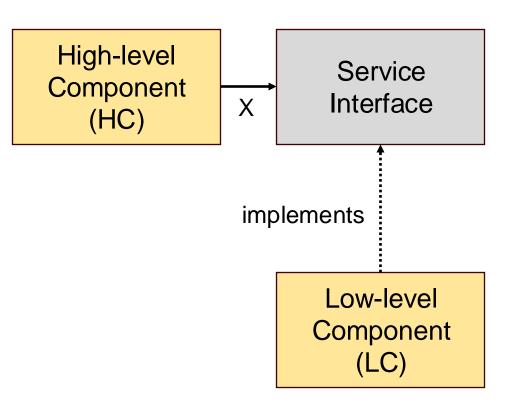

• Q. Does this design violate DIP?

Stock Tracker App: New Design

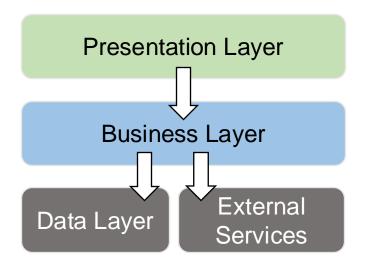

- Generator interface: Hides the type of output file (HTML/RTF) from Formatter
- Formatter: Encodes which part of the quote should be bolded, italicized; does not know anything about HTML/RTF!
- Formatter (high-level component) no longer depends on the generators (low-level components)

- Invert the dependency from HC to LC by introducing an intermediate abstraction (e.g., an interface)
- HC & LC both depend this abstraction
- HC does not know anything about LC
- Goal: When LC changes, minimize its impact on the high-level component
- Q. What assumption(s) is this principle making? Do they hold in practice?

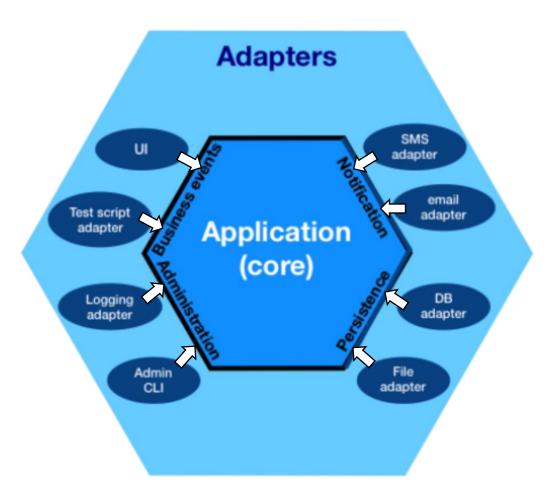

Dependency Inversion in Practice

Traditional Layered Architecture

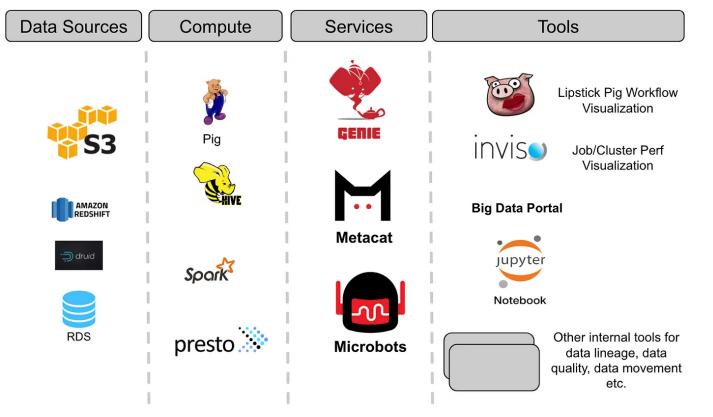

- Common 3-layer pattern for application architecture
- **Top-down dependency**: Higher-level components depend on lower-level ones
- Presentation layer: User facing components (UI, APIs, command line...)
- Business layer: Implements the core application logic
- Q. Potential downside (w.r.t. changeability?)

Alternative Design: Hexagonal Architecture

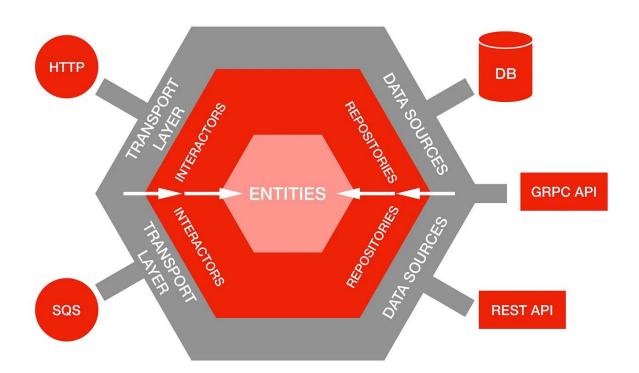

- Inward dependency only: All components depend on core business logic (dependency inversion!)
- Adapter: An implementation of an interact in the core logic
 - Link between an external component & the interface
- Input adapters: Allow users, external actors, and client services to interact with the core logic
- Output adapters: Wrappers for services used by the core logic (e.g., database engine)

- Many different data sources, external services, tools
- Data about movies, production dates, employees, shooting locations (> 300 DB tables)
- Multiple protocols: gRPC, JSON API, GraphQL...
- Challenge: Swap data sources without affecting the core business logic

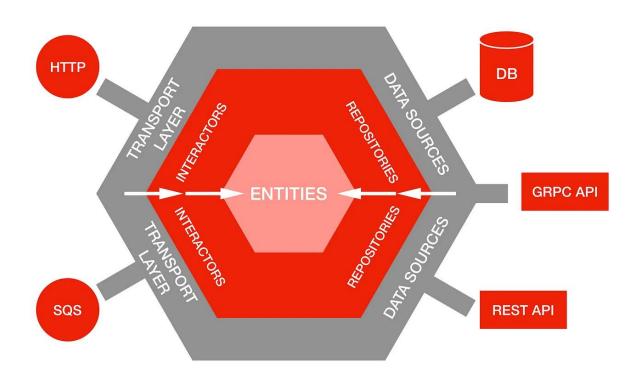

https://netflixtechblog.com/metacat-making-big-data-discoverable-and-meaningful-at-netflix-56fb36a53520

Hexagonal Architecture at Netflix

- Entities: Business objects (e.g., Movie or Shooting Location); knows nothing about how they are stored
- **Repositories:** Interfaces to create, retrieve, and modify entities from a data source
- Interactors: Logic that uses entities to carry out a business use case (e.g., initiate a new movie production)

Hexagonal Architecture at Netflix

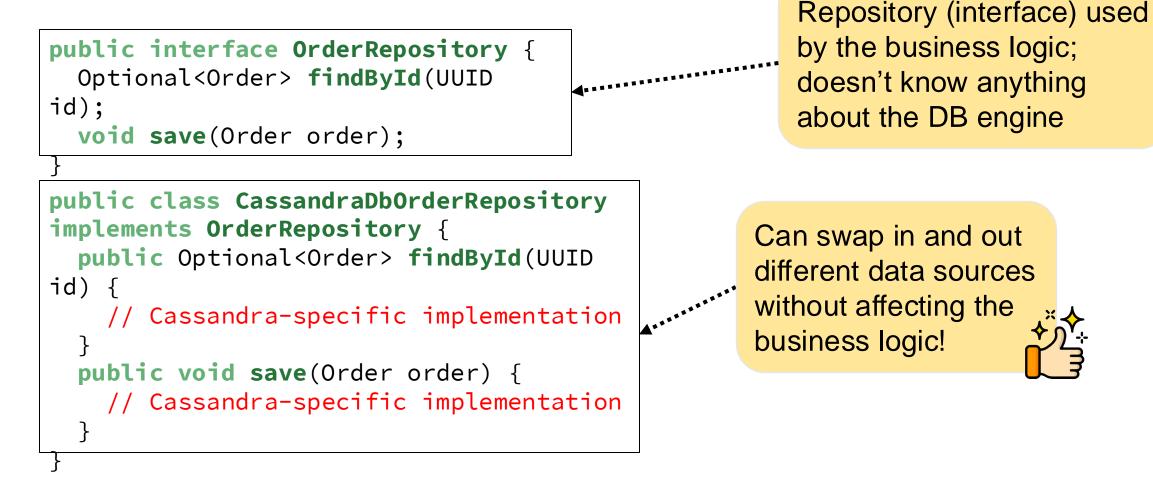

- Data sources: Output adapters; interface with different storage implementations (e.g., SQL, REST API, gRPC)
- Transport layer: Input adapters; triggers a business use case; separates input modes (e.g., HTTP) from the interactors

Adapters: Example

<pre>public interface OrderRepository { Optional<order> findById(UUID id); void save(Order order);</order></pre>	••••••	by the business logic; doesn't know anything about the DB engine
<pre>} public class MongoDbOrderRepository implements OrderRepository { public Optional<order> findById(UU</order></pre>	ID	
<pre>id) { // MongoDB-specific implementati } public void save(Order order) { // MongoDB-specific implementati }</pre>	◀	An adapter that implements the repository interface; wraps details specific to a data source (e.g., MongoDB)
}		

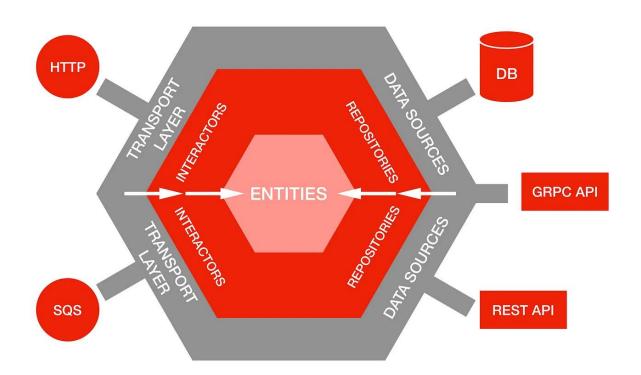

Repository (interface) used

Adapters: Example

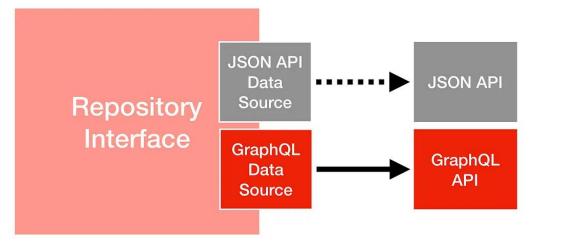

We will come back to adapters again!

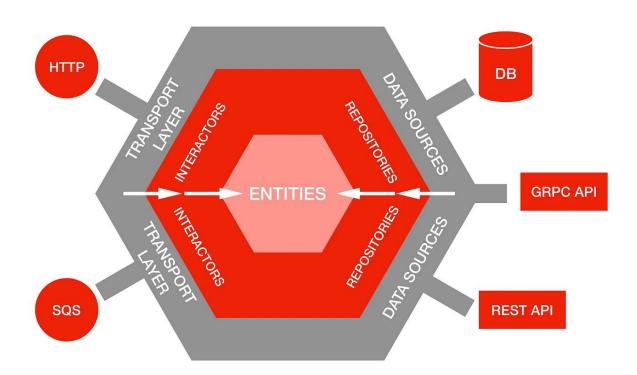

https://netflixtechblog.com/ready-for-changes-with-hexagonal-architecture-b315ec967749

- Q. What are benefits of this architecture?
- Core logic does not know anything about transport layer or data sources
- Can add a new user interaction (e.g., command line) or data sources without changing the business logic

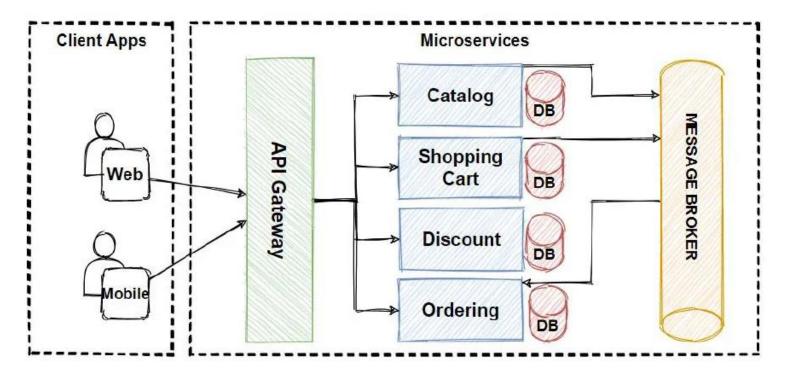

- Can change data sources without impacting core logic, as long as they conform to repositories
- "We managed to transfer reads from JSON API to GraphQL data source within 2 hours."
- No leakage of secrets about data persistence into the business logic!
- Also improves scalability & testability (Q. how so?)

- Q. What are benefits of this architecture?
- Q. What are some limitations? When does this approach not work well?

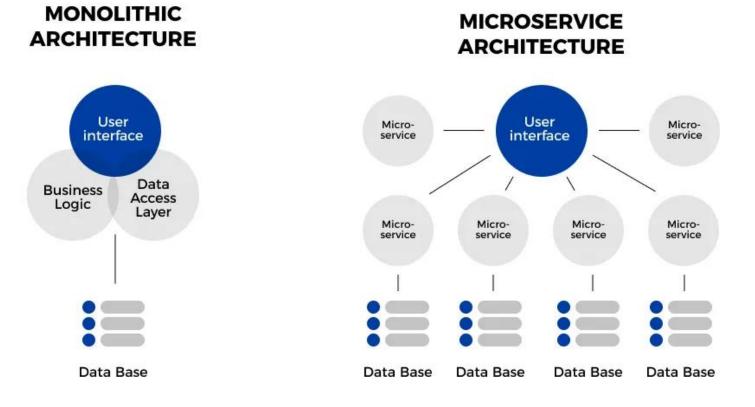

Cost of Modularization

Microservice Architecture

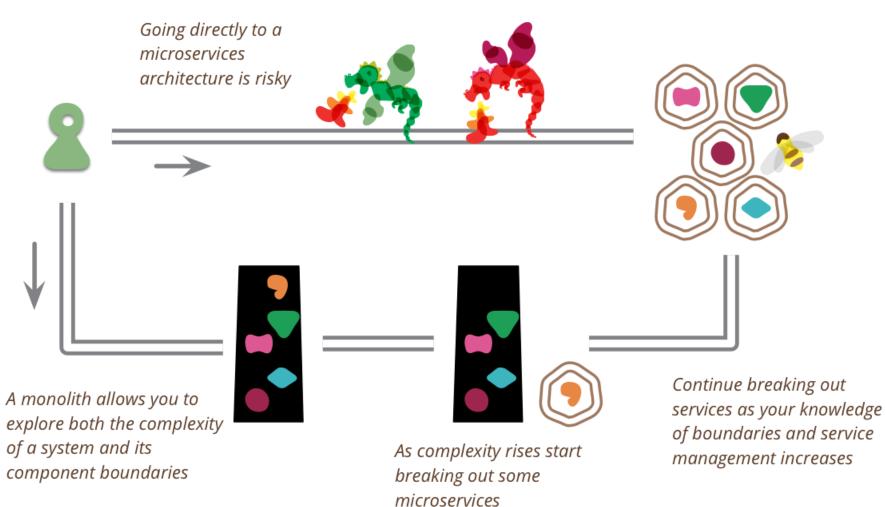

- Decompose system into multiple, deployable units of services, typically developed by independent teams
- User requests are routed to the appropriate service
- Services communicate directly or through a message broker

Microservice Architecture

- Q. What are the benefits of a microservice architecture?
- Q. What are its potential downsides?

"Monolith First"

https://martinfowler.com/bliki/MonolithFirst.html#footnote-typical-monolith

Cost of Modularization: Takeaway

- Like other quality attributes, changeability comes with costs and trade-offs
- Modularization & abstraction, in general, are good practices
- But too much modularization can be harmful
 - Can increase complexity, add development costs, affect performance, and make certain changes even harder to make
- Recall: Risk-driven design!
 - What are likely changes in my system that I need to be ready for?
 - How important is the flexibility to adapt to these changes?
 - Is the lack of flexibility the most significant risk to my product right now?

Summary of Principles & Methods

- Information Hiding: Secrets that are likely to change should be hidden from other components
- Single Responsibility: A component should be responsible for fulling a single purpose only
- Interface Segregation: An interface should not force clients to depend on unnecessary details
- Dependency Inversion: A high-level component should not depend directly on a low-level component
- Data Abstraction: Hide details of a data representation
- Interface Abstraction: Hide details of a service implementation
- Encapsulation: Isolate & hide a secret in one place within the system

• Exit ticket!
